EXPERIENCE

Software Development Engineer 26-JUL 2021 TO 26-AUG 2023

Decimal Point Analytics Pvt. Ltd.

Created T-SQL statements, stored procedures, and functions in SSMS. Worked on HIG and Curinos projects, and trained freshers on SQL and Pentaho pipelines.

Graduate Engineer 18-FEB 2025 TO 17-NOV 2025

Railtel Corporation of India Ltd

Handled operation and maintenance, feasibility and implementation, and data entry tasks.

PROJECTS

ACTIVE ASSESSMENT

Welcome to the SkillPivot Technical Assessment Demo.

I've selected **SQL** for your evaluation today.

Imagine you are working with a high-volume activity tracking database for a fitness app. You have a table named 'UserLogins' with two primary columns: 'user_id' (UUID) and 'login_date' (DATE).

Your task is to write a query that identifies the **longest consecutive daily login streak** for every user.

Could you walk me through the logic of how you would solve this using window functions? Additionally, since this table contains hundreds of millions of rows, what specific strategies would you implement to ensure the query is performant and doesn't exhaust tempdb or memory?

<> TYPE ANSWER

I would use ROW_NUMBER() partitioned by 'user_id' ordered by 'login_date', then subtract row number from login date to form groups of consecutive days. After grouping, I'd count each streak and use RANK() to identify the longest streak per user.

INTERMEDIATE

EXPERT FEEDBACK

"Your logical approach to the consecutive streak problem is accurate and demonstrates a solid understanding of window function arithmetic. However, as a technical examiner, I must note that you omitted the critical performance engineering component of the question. For a table with hundreds of millions of rows, a simple window function across the whole set would likely cause a massive sort spill to tempdb or a memory exhaustion error without proper indexing, pre-filtering, or partitioning strategies."

PARTIALLY CORRECT

1

Welcome to the SAIPIVOT Technical Assessment Demo.

I've selected "P002" for your evaluation today.

Imagine you are working with a high-revenue authority tracking database for a threat data file base table named "tracklog" with two primary columns: "user_id" (UUID) and "high_auth" (ENUM).

Your task is to write a query that identifies the "largest consecutive delay high auth" for every user.

Could you walk me through the logic of how you would solve this using window functions? Additionally, since this table contains hundreds of millions of rows, what specific strategies would you implement to ensure the query is performant and doesn't exhaust tempdb or memory?

Insert one ROW_ID, ROW_NUMBER() partitioned by "user_id" ordered by "high_auth", then between two ordered "high_auth" data to help groups of consecutive data, then grouping by user, then window count and use ROWS() to identify the longest streak per user.

2

ANALYSIS

"Your logical approach to the consecutive offset problem is accurate and demonstrates a solid understanding of window function arithmetic. However, as a technical assessment, I must note that your solution did not fully address the performance engineering component of the question. For a table with hundreds of millions of rows, a simple window function across the entire set would likely cause a massive row spill to tempdb or a memory allocation error without proper indexing, pre-filtering, or partitioning strategies."

ANALYSIS SUMMARY

3

KEY STRATEGIES

Identified the "Time and Space" high correctly using ROWS() to identify consecutive rows.

Effectively explained the grouping mechanism for consecutive data exposure.

4

DETAILED NOTES

Conceptually ignored the performance implications of the overall grouping mechanism on 100M+ rows.

Did not explore handling potential duplicate high_auth per user on the same day which would break the ROWS() assumption.

Failed to address memory management or tempdb spill prevention strategies.

100% GROWTH PLAN

Technical Assessment Score 5/10

41

CRITICAL FOCUS

DB: Performance Tuning at Scale

Query Execution Plan Analysis

Memory and Data I/O Management in SQL

42

RECOMMENDED TOPICS

Converting Indexes used in True Analytics

Partitioning SQL Query and the Impact on window Functions

Window Functions optimization (Pivot, Rank, or Order Rank)

43

SKILL EXERCISES

Transfer the above window function to SQL Server and compare the results.

Design an execution plan for a query with a large table and a window function.

Implement a partitioned view and write a query to utilize it for a more efficient access.

44

Next Steps

Review the detailed breakdown of how SQL engine processes window functions and explore the "Segment" and "Sequence" engine operations in execution plans to understand how to optimize them.
